Pathophysiology. The use of tobacco may also increase the risk for caries formation. Some brands of smokeless tobacco contain high sugar content, increasing susceptibility to caries. Tobacco use is a significant risk factor for periodontal disease, which can cause the gingiva to recede.[62] As the gingiva loses attachment to the teeth,...

In addition, there is a vast body of evidence that give great importance to the role of saliva in the development of caries. The role of saliva in the self-cleaning of the tooth surface, the pH regulation and control of oral microflora have the ability to reduce the cariogenic potential of the dental plaque [5,6].

Caries activity increases as the viscosity of the saliva increases. Eating fibrous food and chewing vigorously increases salivation, which helps in digestion as well as improves cleansing of the teeth. The quantity as well as composition, pH, viscosity and buffering capacity of the saliva plays a role in dental caries.

Enamel. As the enamel loses minerals, and dental caries progresses, the enamel develops several distinct zones, visible under a light microscope. From the deepest layer of the enamel to the enamel surface, the identified areas are the: translucent zone, dark zones, body of the lesion, and surface zone.
